

Chapter 8

Waves and Water Dynamics

Introductory Oceanography
10th Edition

Wave characteristics and terminology

- Crest
- Trough
- Wave height (H)
- Wavelength (L)
- Still water level
- Orbital motion

B.

Figure 8-3b

What causes waves?

- Waves are created by releases of energy (disturbances) including:
 - ❑ Wind
 - ❑ Movement of fluids of different densities
 - ❑ Mass movement into the ocean (splash waves)
 - ❑ Underwater sea floor movement (tsunami)
 - ❑ Pull of the Moon and Sun (tides)
 - ❑ Human activities

Most ocean waves are wind-generated

The medium itself
(solid, liquid, gas) does
NOT actually travel in
the direction of energy

Figure 8-2

Types of progressive waves

● Longitudinal

▣ Back-and-forth motion

● Transverse

▣ Side-to-side motion

● Orbital

▣ Combination

Types of progressive waves

LONGITUDINAL WAVE
Particles (color) move back and forth in direction of energy transmission. These waves transmit energy through all states of matter.

TRANSVERSE WAVE
Particles (color) move back and forth at right angles to direction of energy transmission. These waves transmit energy only through solids.

ORBITAL WAVE
Particles (color) move in orbital path. These waves transmit energy along interface between two fluids of different density (liquids and/or gases).

Wave characteristics and terminology (continued)

- Wave steepness = $\frac{\text{wave height } (H)}{\text{wavelength } (L)}$

- ▣ If wave steepness exceeds $1/7$, the wave breaks

- Period (T) = the time it takes one full wave—one wavelength—to pass a fixed position

- Frequency (f) = $\frac{1}{T}$

Circular orbital motion

- As a wave travels, the water passes the energy along by moving in a circular orbit
- Floating objects also follow circular orbits

Figure 8-4

Orbital motion in waves

- Orbital size decreases with depth to zero at wave base
- Depth of wave base = $\frac{1}{2}$ wavelength, measured from still water level

Figure 8-5

Deep- and shallow-water waves

● Deep-water waves

- ❑ Water depth $>$ wave base

● Shallow-water waves

- ❑ Water depth $< \frac{1}{20}$ of wavelength

● Transitional waves

- ❑ Water depth $<$ wave base but also $> \frac{1}{20}$ of wavelength

(a) Deep-water wave

(b) Shallow-water wave

Figure 8-6a & b

Wave speed (S)

- General formula: Wave speed (S) = $\frac{\text{wavelength } (L)}{\text{period } (T)}$
- Deep-water waves:
 - ❑ Wave speed (S) in meters per second = $1.56 T$ in seconds
 - ❑ Wave speed (S) in feet per second = $5.12 T$ in seconds
- Shallow-water waves: (d = water depth)
 - ❑ Wave speed (S) in meters per second = $3.13\sqrt{d}$ in meters
 - ❑ Wave speed (S) in feet per second = $5.67\sqrt{d}$ in feet

The “sea” and swell

- Waves originate in a “sea” area
- The area where wind-driven waves are generated

Figure 8-9

The “sea” and swell

● **Swell** describes waves that:

- ❑ Have traveled out of their area of origination (**wind has no more effect**)
- ❑ Exhibit a uniform and symmetrical shape
- ❑ Long wavelength - surface waves (group)
 - traveled long distances
 - (more stable than wind waves)

Figure 8-9

From Calm to Fully Developed Sea

❖ IT all starts with the Wind → swells

Fully developed sea

- Factors that increase wave height:
 - ✦ Increasing wind speed
 - ✦ Increasing duration (time) of wind
 - ✦ Increasing fetch (distance)
- A **fully developed sea** is the maximum height of waves produced by conditions of wind speed, duration, and fetch

Largest wind-generated waves authentically recorded

- In 1935, the vessel *USS Ramapo* experienced large waves while crossing the Pacific Ocean
- Wave height was measured at 34 meters (112 feet)

Figure 8-11

Interference patterns

● Constructive

▣ Increases
wave height

● Destructive

▣ Decreases
wave height

● Mixed

▣ Variable
pattern

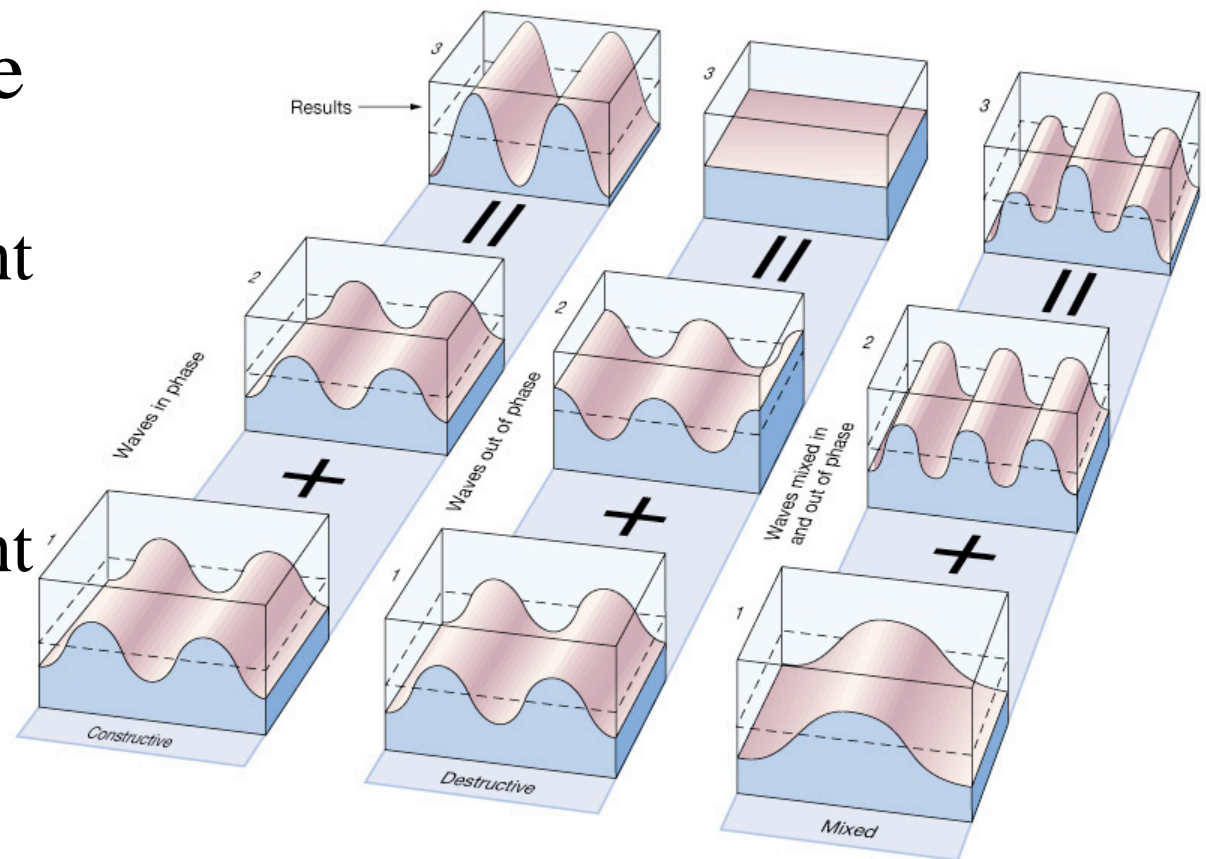

Figure 8-13

Waves undergo physical changes in the surf zone

Figure 8-15

Types of breakers

● Spilling breakers

- ❑ Gentle beach slope allows waves to disperse energy gradually

SPILLING BREAKERS

● Plunging breakers

- ❑ Moderately steep beach slope gives waves a curling shape that propels surfers

PLUNGING BREAKERS

● Surging breakers

- ❑ Abrupt beach slope makes waves build up and break rapidly at the shore

SURGING BREAKERS

Wave refraction

- As waves approach shore, the part of the wave in shallow water slows down
- The part of the wave in deep water continues at its original speed
- Causes wave crests to **refract** (bend)
- Results in waves lining up nearly parallel to shore

Wave refraction along a straight shoreline

https://www.youtube.com/watch?v=xwzw5GhpC_0

Figure 8-17

Wave refraction along an irregular shoreline

- Orthogonal lines denote areas of equal wave energy
- Wave energy is concentrated at headlands and dispersed in bays

Figure 8-18

Wave reflection

- Wave energy is **reflected** (bounced back) when it hits a solid object
- Wave reflection produces large waves at “The Wedge” near Newport Harbor, California

Figure 8-19

Tsunami

● Tsunami terminology

- ❑ Often called “tidal waves” but have nothing to do with the tides
- ❑ Japanese term meaning “harbor wave”
- ❑ Also called “seismic sea waves”

● Created by movement of the ocean floor by:

- ❑ Underwater fault movement
- ❑ Underwater avalanches
- ❑ Underwater volcanic eruptions

Most tsunamis originate from underwater fault movement

<https://www.youtube.com/watch?v=SlwZzbGh7Cw>

<https://www.youtube.com/watch?v=Wx9vPv-T51I>

Figure 8-21a

Tsunami characteristics

- Affect entire water column, so carry more energy than surface waves
- Can travel at speeds over 700 kilometers (435 miles) per hour
- Small wave height in the open ocean, so pass beneath ships unnoticed
- Build up to extreme heights in shallow coastal areas

Coastal effects of tsunami

- If trough arrives first, appear as a strong withdrawal of water (similar to an extreme and suddenly-occurring low tide)
- If crest arrives first, appear as a strong surge of water that can raise sea level many meters and flood inland areas
- Tsunami often occur as a series of surges and withdrawals

Tsunami since 1900

- Most tsunami are created near the margins of the Pacific Ocean along the Pacific “Ring of Fire”

- [Internet video of tsunami movement across Pacific Ocean](#)

Figure 8-23

Tsunami warning system

- Seismic listening stations track underwater earthquakes that could produce tsunami
- Once a large earthquake occurs, the tsunami must be verified at a nearby station
- If verified, a tsunami warning is issued
- Successful in preventing loss of life (if people heed warnings)
- Damage to property has been increasing

Coastal wave energy resources
